11		5.3 Output column Date_BC_AD_Sample	3
12	6	General helper functions	3

13 1 Installation

See the Poseidon website (https://www.poseidon-adna.org/#/janno_r_package) or the GitHub repository (https://github.com/poseidon-framework/janno) for up-to-date installation instructions.

$_{\scriptscriptstyle 16}$ $\, \, { m Read} \,$. janno files

17 You can read . janno files with

```
my_janno_object <- janno::read_janno(
  path = "path/to/my/janno_file.janno",
  to_janno = TRUE,
  validate = TRUE
)</pre>
```

- The path argument takes one or multiple file paths or directory paths. read_janno() searches recursively for .janno files in these directory paths.
- Before loading the .janno files they are validated with janno::validate_janno(). You can avoid this potentially time consuming step with validate = FALSE.
- Usually the .janno files are first loaded as normal .tsv files with every column type set to character and then
- 23 the columns are transformed to the specified types. This transformation can be turned off with to_janno =

24 FALSE.

²⁵ read_janno() returns an object of class janno. This class is derived from the tibble class, which integrates

well with the tidyverse [1] and its packages, e.g. dplyr or ggplot2.

²⁷ 3 Validate . janno files

28 You can validate . janno files with

```
my_janno_issues <- janno::validate_janno("path/to/my/janno_file.janno")</pre>
```

validate_janno returns a tibble with issues in the respective .janno files. For edge cases this validation may

yield slightly different results than trident validate.

31 4 Write janno objects back to .janno files

32 janno objects usually contain list columns, that can not directly be written to a flat text file like the .janno

33 file. The function write_janno solves that. It employs a helper function flatten_janno(), which translates list

columns to the string list format in .janno files (so: multiple values for one cell separated by ;).

This only works for vector list columns, so when each cell contains a vector of values. If a list column contains

other data structures, e.g. data.frames, they will be dropped and replaced with the NULL value n/a in the

37 resulting .janno file.

```
janno::write_janno(
  my_janno_object,
  path = "path/to/my/new/janno_file.janno"
)
```

5 Process age information in janno objects

 $_{39}$. janno files contain age information in multiple different columns. See the . janno file specification and docu-

mentation for a list and detailed explanations of these variables. The function janno::process_age() works

with this age information to calculate different derived columns, which are then added to the input janno object.

42 You can run it with

```
janno::process_age(
  my_janno_object,
  choices = c("Date_BC_AD_Prob", "Date_BC_AD_Median_Derived", "Date_BC_AD_Sample"),
  n = 100,
  cal_curve = "intcal20"
)
```

⁴³ process_age() includes calibration of radiocarbon dates with the Bchron R package [2]. The calibration curve

set in cal_curve is applied for every date in the janno object. If there are multiple radiocarbon dates for one

sample they are automatically combined as the normalized sum of all individual post-calibration probability

46 distributions.

- 47 The choices argument contains the list of columns that should be calculated and added by process_age(). n
- is the number of samples that should be drawn for Date_BC_AD_Sample.

49 5.1 Output column Date_BC_AD_Prob

Date_BC_AD_Prob is a list column with a data.frame for each janno row, so each individual/sample. This
data.frame stores a density distribution (sum_dens) over a set of years BC/AD (age). Additionally the boolean
column two_sigma documents if a given year is within the 2-sigma high-density regions of the distribution.
center is also a boolean column with only one TRUE value for the year that corresponds to the calibrated median
age of the sample.

age	sum_dens	two_sigma	center
-1506	0.00000456	FALSE	FALSE
-1505	0.00000622	FALSE	FALSE
-1504	0.00000907	FALSE	FALSE

- 55 The density distributions are either the result of (sum) calibration on radiocarbon dates or for samples that
- ₅₆ are only contextually dated a uniform distribution over the archaeologically determined age range.

5.2 Output column Date_BC_AD_Median_Derived

- $\tt Date_BC_AD_Median_Derived$ is a simple integer column with the median age (in years BC/AD) as determined
- 59 from Date_BC_AD_Prob.

5.3 Output column Date_BC_AD_Sample

- Date_BC_AD_Sample is again a list column with a vector of n ages (in years BC/AD) for each .janno file
- individual/sample. These ages are randomly drawn with base::sample(prob = ...) using the probability
- 63 distribution calculated for Date_BC_AD_Prob.

6 General helper functions

- When you are preparing a .janno file and want to determine the entries for the columns Date_BC_AD_Median,
- 66 Date_BC_AD_Start and Date_BC_AD_Stop from radiocarbon dates, then janno::quickcalibrate() might come
- 67 in handy.

```
janno::quickcalibrate(ages, sds)
```

- ages takes a list of uncalibrated C14 ages BP and sds a list of the respective standard deviations. If multiple
- ₆₉ ages are provided for one sample, then the function automatically performs a sum calibration.
- $_{70}$ quickcalibrate(list(1000, c(2000, 2200)), list(20, c(30, 40))) for example returns a data.frame
- 71 like this:

Date_BC_AD_Start_2Sigma	 ${\tt Date_BC_AD_Median}$	 Date_BC_AD_Stop_2Sigma
994	 1029	 1149

Date_BC_AD_Start_2Sigma	 Date_BC_AD_Median	 Date_BC_AD_Stop_2Sigma
-383	 -88	 117

This output can be copied to a .janno file, where Date_BC_AD_Start_2Sigma corresponds to Date_BC_AD_Start, and Date_BC_AD_Stop_2Sigma to Date_BC_AD_Stop.
