1 The trident CLI

Trident is a command line software tool structured in multiple subcommands. If you installed it properly you can call it on the command line by typing trident. This will show an overview of the general options and all subcommands, which are explained in detail below.

trident is a management and analysis tool for Poseidon packages. Report issues here: https://github.com/poseidon-framework/poseidon-hs/issues

Available options:

-h,--help Show this help text --version Show version number

--logMode MODE How information should be reported: NoLog, SimpleLog,

DefaultLog, ServerLog or VerboseLog.

```
(default: DefaultLog)
```

--debug Short for --logMode VerboseLog.

--errLength INT After how many characters should a potential error

message be truncated. "Inf" for no truncation.

(default: CharCount 1500)

--inPlinkPopName MODE Where to read the population/group name from the FAM

file in Plink-format. Three options are possible:

asFamily (default) | asPhenotype | asBoth.

Package creation and manipulation commands:

init Create a new Poseidon package from genotype data fetch Download data from a remote Poseidon repository forge Select packages, groups or individuals and create a

new Poseidon package from them

genoconvert Convert the genotype data in a Poseidon package to a

different file format

rectify Adjust POSEIDON.yml files automatically to package

changes

Inspection commands:

list List packages, groups or individuals from local or

remote Poseidon repositories

summarise Get an overview over the content of one or multiple

Poseidon packages

survey Survey the degree of context information completeness

for Poseidon packages

validate Check Poseidon packages or package components for

structural correctness

Trident allows to work directly with genotype data (see -p below), but its optimized for the interaction with Poseidon packages, which wrap and contextualize the data. Most trident subcommands therefore have a central parameter, called --baseDir or simply -d to specify one or more base directories to look for packages. For example, if all Poseidon packages live inside a repository at /path/to/poseidon/packages you would simply say trident <subcommand> -d /path/to/poseidon/dirs/ and trident would automatically search all subdirectories inside of the repository for valid Poseidon packages (as identified by valid POSEIDON.yml files).

You can arrange a poseidon repository in a hierarchical way. For example:

You can use this structure to select only the level of packages you're interested in, even individual ones, and you can make use of the fact that -d can be given multiple times.

Being able to specify one or multiple repositories is often not enough, as you may have your own data to co-analyse with the main repository. This is easy to do, as you simply need to provide your own genotype data as yet another Poseidon package to be added to your trident command. For example, let's say you have genotype data in EIGENSTRAT format (trident supports EIGENSTRAT and PLINK as formats.):

```
~/my_project/my_project.geno
~/my_project/my_project.snp
~/my_project/my_project.ind
```

then you can make that to a skeleton Poseidon package with the **init** command. You can also do it manually by simply adding a POSEIDON.yml file, with for example the following content:

```
poseidonVersion: 2.7.1
title: My_awesome_project
description: Unpublished genetic data from my awesome project
contributor:
   - name: Stephan Schiffels
        email: schiffels@institute.org
packageVersion: 0.1.0
lastModified: 2020-10-07
genotypeData:
   format: EIGENSTRAT
   genoFile: my_project.geno
   snpFile: my_project.snp
   indFile: my_project.ind
jannoFile: my_project.janno
bibFile: sources.bib
```

Two remarks: 1) all file paths are considered *relative* to the directory in which POSEIDON.yml resides. For this example we assume that this file is added into the same directory as the three genotype files. 2) Besides the genotype data files there are two (technically optional) files referenced by this example POSEIDON.yml file: sources.bib and my_project.janno. Of course you can add them manually - init automatically creates empty dummy versions.

Once you have set up your own Poseidon package (which is really only a skeleton so far), you can add it to your trident analysis, by simply adding your project directory to the command using -d, for example:

```
trident list -d /path/to/poseidon/packages/modern \
  -d /path/to/poseidon/packages/ReferenceGenomes
  -d ~/my_project --packages
```

1.1 General notes

1.1.1 Logging and command line output

For all subcommands the general argument --logMode defines how trident reports messages (to stderr) on the command line:

- NoLog: Hides all messages.
- SimpleLog: Plain and simple output to stderr.
- DefaultLog: Adds severity indicators before each message. (default setting)
- ServerLog: Additionally adds timestamps before each message.
- VerboseLog: Shows not just messages on the log levels Info, Warning and Error like the other modes, but also on the more verbose level Debug. Use this for debugging.

--debug is short for --logMode VerboseLog to activate this important log level more easily.

1.1.2 Duplicates

• If multiple packages in a package repository share the same title, then trident will try to select the one with the highest version number. If this is not sufficient to resolve the conflict, trident will stop. An exception for that is the list subcommand, which will read and report all packages/groups/individuals in all versions.

- Individual/sample names (Poseidon_IDs) within one package have to be unique, or trident will stop.
- We generally also discourage ID duplicates across packages in package repositories, but trident will generally continue with them after printing a warning. This does not apply for validate, by default (you can change this behaviour with --ignoreDuplicates), and forge. forge offers a special mechanism to resolve duplicates within its selection language (see below).

1.1.3 Group names in .fam files

The .fam file of Plink-formatted genotype data is used inconsistently across different popular aDNA software tools to store group/population name information. The (global) option --inPlinkPopName with the arguments asFamily (default), asPhenotype and asBoth allows to control the reading of the population name from Plink .fam files. The subcommands that write genotype data (forge, genoconvert) have a corresponding option --outPlinkPopName to specify this for the output.

1.1.4 Whitespaces in the .janno file

While reading the .janno file trident trims all leading and trailing whitespaces around individual cells. Also all instances of the No-Break Space unicode character will be removed. This means these whitespaces will not be preserved when a package is forged.

2 Package creation and manipulation commands

2.1 Init command

init creates a new, valid Poseidon package from genotype data files. It adds a valid POSEIDON.yml file, a dummy .janno file for context information and an empty .bib file for literature references.

Click here for command line details

```
Usage: trident init ((-p|--genoOne FILE) | --inFormat FORMAT --genoFile FILE --indFile FILE) [--snpSet SET]

(-o|--outPackagePath DIR) [-n|--outPackageName STRING]

[--minimal]
```

Create a new Poseidon package from genotype data

Available options:

-h,--help Show this help text -p,--genoOne FILE One of the input genotype data files. Expects .bed, .bim or .fam for PLINK and .geno, .snp or .ind for EIGENSTRAT. The other files must be in the same directory and must have the same base name. --inFormat FORMAT The format of the input genotype data: EIGENSTRAT or PLINK. Only necessary for data input with --genoFile + --snpFile + --indFile. --genoFile FILE Path to the input geno file. Path to the input snp file. --snpFile FILE --indFile FILE Path to the input ind file. --snpSet SET The snpSet of the package: 1240K, HumanOrigins or Other. Only relevant for data input with -p|--genoOne or --genoFile + --snpFile + --indFile, because the packages in a -d|--baseDir already have this information in their respective POSEIDON.yml files. (default: Other) -o, -- outPackagePath DIR Path to the output package directory.

```
-n, -- outPackageName STRING
```

The output package name. This is optional: If no name is provided, then the package name defaults to the basename of the (mandatory) --outPackagePath argument. (default: Nothing)

Should the output data be reduced to a necessary minimum and omit empty scaffolding?

The command

--minimal

```
trident init \
   --inFormat EIGENSTRAT/PLINK \
   --genoFile path/to/geno_file \
   --snpFile path/to/snp_file \
   --indFile path/to/ind_file \
   --snpSet 1240K|HumanOrigins|Other \
   -o path/to/new_package_name
```

requires the format (--inFormat) of your input data (either EIGENSTRAT or PLINK), the paths to the respective files (--genoFile, --snpFile, --indFile), and optionally the "shape" of these files (--snpSet), so if they cover the 1240K, the HumanOrigins or an Other SNP set. A simpler interface is available with -p (+ --snpSet).

	EIGENSTRAT	PLINK
genoFile	.geno	.bed
snpFile	.snp	.bim
indFile	.ind	.fam

The output package of init is created as a new directory -o, which should not already exist, and gets the package title corresponding to the basename of -o. You can also set the title explicitly with -n. The --minimal flag causes init to create a minimal package with a very basic POSEIDON.yml and no .bib and .janno files.

2.2 Fetch command

fetch allows to download Poseidon packages from a remote Poseidon server via a Web API. Read more about the data available with it here.

Click here for command line details

Download data from a remote Poseidon repository

```
Available options:
```

-h,--help Show this help text
-d,--baseDir DIR A base directory to search for Poseidon packages.
--downloadAll Download all packages the server is offering.
--fetchFile FILE A file with a list of packages. Works just as -f, but multiple values can also be separated by newline, not just by comma. -f and --fetchFile can be combined.
-f,--fetchString DSL List of packages to be downloaded from the remote server. Package names should be wrapped in asterisks:

package_title. You can combine multiple values with comma, so for example: "*package_1*, *package_2*, *package_3*". fetchString uses the same parser as forgeString, but does not allow excludes. If groups or individuals are specified, then packages which include these groups or individuals are included in the download.

--remoteURL URL

URL of the remote Poseidon server.

--archive STRING

(default: "https://server.poseidon-adna.org")
The name of the Poseidon package archive that should
be queried. If not given, then the query falls back
to the default archive of the server selected with
--remoteURL. See the archive documentation at
https://www.poseidon-adna.org/#/archive_overview for
a list of archives currently available from the
official Poseidon Web API. (default: Nothing)

It works with

```
trident fetch -d ... -d ... \
   -f "*package_title_1*,*package_title_2*,*package_title_3*,group_name,<individual1>"
```

and the entities you want to download must be listed either in a simple string of comma-separated values, which can be passed via -f/--fetchString, or in a text file (--fetchFile). Entities are then combined from these sources.

Entities are specified using a special syntax (see also the documentation of forge below): Package titles are wrapped in asterisks: *package_title*, group names are spelled as is, and individual names are wrapped in angular brackets, so <individual1>. Fetch will figure out which packages need to be downloaded to include all specified entities. --downloadAll, which can be given instead of -f and --fetchFile, causes fetch to download all packages from the server. The downloaded packages are added in the first (!) -d directory (which gets created if it doesn't exist), but downloads are only performed if the respective packages are not already present in the latest version in any of the -d dirs.

Note that trident fetch makes most sense in combination with trident list --remote: First one can inspect what is available on the server, then one can create a custom fetch command.

fetch also has the optional arguments --remote https:://..." to name an alternative Poseidon server and --archive to select a Poseidon archive on the server. Here is a list of the archives available on the official Poseidon server.

2.3 Forge command

forge creates new Poseidon packages by extracting and merging packages, populations and individuals from your Poseidon repositories.

Click here for command line details

Select packages, groups or individuals and create a new Poseidon package from them

Available options:

-h,--help

-d,--baseDir DIR

-p,--genoOne FILE

--inFormat FORMAT

--genoFile FILE

--snpFile FILE

--indFile FILE

--snpSet SET

--forgeFile FILE

-f,--forgeString DSL

--selectSnps FILE

Show this help text

A base directory to search for Poseidon packages. One of the input genotype data files. Expects .bed, .bim or .fam for PLINK and .geno, .snp or .ind for EIGENSTRAT. The other files must be in the same directory and must have the same base name.

The format of the input genotype data: EIGENSTRAT or PLINK. Only necessary for data input with --genoFile + --snpFile + --indFile.

Path to the input geno file. Path to the input snp file.

Path to the input ind file.

The snpSet of the package: 1240K, HumanOrigins or Other. Only relevant for data input with -p|--genoOne or --genoFile + --snpFile + --indFile, because the packages in a -d|--baseDir already have this information in their respective POSEIDON.yml files.

(default: Other)

A file with a list of packages, groups or individual samples. Works just as -f, but multiple values can also be separated by newline, not just by comma. Empty lines are ignored and comments start with "#", so everything after "#" is ignored in one line. Multiple instances of -f and --forgeFile can be given. They will be evaluated according to their input order on the command line.

List of packages, groups or individual samples to be combined in the output package. Packages follow the syntax *package_title*, populations/groups are simply group_id and individuals <individual_id>. You can combine multiple values with comma, so for example: "*package_1*, <individual_1>, <individual_2>, group_1". Duplicates are treated as one entry. Negative selection is possible by prepending "-" to the entity you want to exclude (e.g. "*package_1*, -<individual_1>, -group_1"). forge will apply excludes and includes in order. If the first entity is negative, then forge will assume you want to merge all individuals in the packages found in the baseDirs (except the ones explicitly excluded) before the exclude entities are applied. An empty forgeString (and no --forgeFile) will therefore merge all available individuals. If there are individuals in your input packages with equal individual id, but different main group or source package, they can be specified with the special syntax "<package:group:individual>".

To extract specific SNPs during this forge operation, provide a Snp file. Can be either Eigenstrat (file ending must be '.snp') or Plink (file ending must be '.bim'). When this option is set, the output package will have exactly the SNPs listed in this file. Any SNP not listed in the file will be excluded. If

option '--intersect' is also set, only the SNPs
overlapping between the SNP file and the forged
packages are output. (default: Nothing)
--intersect Whether to output the intersection of the genotype

files to be forged. The default (if this option is not set) is to output the union of all SNPs, with genotypes defined as missing in those packages which do not have a SNP that is present in another package. With this option set, the forged dataset will typically have fewer SNPs, but less missingness.

--outFormat FORMAT The format of the output genotype data: EIGENSTRAT or

PLINK. (default: PLINK)

--minimal Should the output data be reduced to a necessary

minimum and omit empty scaffolding?

--onlyGeno Should only the resulting genotype data be returned?

This means the output will not be a Poseidon package.

-o, -- outPackagePath DIR Path to the output package directory.

-n,--outPackageName STRING

The output package name. This is optional: If no name is provided, then the package name defaults to the basename of the (mandatory) --outPackagePath

argument. (default: Nothing)

--packagewise Skip th

Skip the within-package selection step in forge. This will result in outputting all individuals in the relevant packages, and hence a superset of the requested individuals/groups. It may result in better performance in cases where one wants to forge entire packages or almost entire packages. Details: Forge conceptually performs two types of selection: First, it identifies which packages in the supplied base directories are relevant to the requested forge, i.e. whether they are either explicitly listed using *PackageName*, or because they contain selected individuals or groups. Second, within each relevant package, individuals which are not requested are removed. This option skips only the second step, but still performs the first.

--outPlinkPopName MODE

Where to write the population/group name into the FAM file in Plink-format. Three options are possible: asFamily (default) | asPhenotype | asBoth. See also --inPlinkPopName.

forge can be used with

```
trident forge -d ... -d ... \
  -f "*package_name*, group_id, <individual_id>" \
  -o path/to/new_package_name
```

where the entities (packages, groups/populations, individuals/samples) you want in the output package can be denoted either as a string on the command line (-f/--forgeString), or in an input text file (--forgeFile). See the section below for the syntax of this selection language. Do not forget to wrap the --forgeString query in quotes.

Including one or multiple Poseidon packages with <code>-d</code> is not the only way to include data for a forge operation. It is also possible to consider unpackaged genotype data directly with <code>-p</code> (<code>+ --snpSet</code>) or <code>--inFormat + --genoFile + --snpFile + --indFile</code> (<code>+ --snpSet</code>). This makes the following example possible, where we merge data from one Poseidon package and two genotype datasets to get a

new EIGENSTRAT dataset.

```
trident forge \
  -d 2017_GonzalesFortesCurrentBiology \
  -p 2018_VeeramahPNAS/2018_VeeramahPNAS.fam \
  --inFormat PLINK \
  --genoFile 2017_HaberAJHG/2017_HaberAJHG.bed \
  --snpFile 2017_HaberAJHG/2017_HaberAJHG.bim \
  --indFile 2017_HaberAJHG/2017_HaberAJHG.fam \
  -f "<STR241.SG>,<ERS1790729.SG>,Iberia_HG.SG" \
  -o testpackage \
  --outFormat EIGENSTRAT \
  --onlyGeno
```

2.3.1 The forge selection language

The text in --forgeString and --forgeFile are parsed as a domain specific query language that describes precisely which entities should be compiled in the output package of a given forge operation. The language has multiple syntactic elements and a specific evaluation logic.

In general a --forgeString query consists of multiple entities, separated by ,. The main entities are Poseidon packages, groups/populations and individuals/samples:

- Each package title is surrounded by *: *package*. That means if you want all individuals of the Poseidon package 2019_Jeong_InnerEurasia in the output package you would add *2019 Jeong InnerEurasia* to the query.
- Groups/populations are not specially marked: group. So to get all individuals of the group Swiss_Roman_period, you would simply add Swiss_Roman_period.
- Individuals/samples are surrounded by < and >: <individual>. ALA026 therefore becomes <ALA026>. A second way to denote individuals is with the more verbose and specific syntax <package:group:individual>. Such defined individuals take precedence over differently defined ones (so: directly with <individual> or as a subset of *package* or group). This allows to resolve duplication issues precisely at least in cases where the duplicated individuals differ in source package or primary group.

In the <code>--forgeFile</code> each line is treated as a separate forgeString, empty lines are ignored and <code>#s</code> start comments. So this is a valid forgeFile:

```
# Packages
*package1*, *package2*

# Groups and individuals from other packages beyond package1 and package2
group1, <individual1>, group2, <individual2>, <individual3>

# group2 has two outlier individuals that should be ignored
-<bad_individual1> # This one has very low coverage
-<bad_individual2> # This one is from a different time period
```

By prepending - to the bad individuals, we can exclude them from the forged package. forge figures out the final list of samples to include by executing all forge-entities in order. So an entity list *PackageA*,-<Individual1>,GroupA may result in a different outcome than *PackageA*,GroupA,-<Individual1>, depending on whether <Individual1> belongs to GroupA or not. If the forge entity list starts with a negative entity, or if the entity list is empty, forge will implicitly assume you want to include all individuals in all packages found in the baseDirs (except the ones explicitly excluded, of course).

An empty forgeString will therefore merge all available individuals.

2.3.2 Treatment of the .janno file while merging

forge merges and subsets .janno files along with the genotype data. If a package lacks a .janno file, then a basic one will be created internally based on the information in the genotype data, and used for the output. Missing columns across packages will be filled with n/a.

For merging two .janno files A and B the following rules apply regarding undefined, arbitrary additional columns:

- If **A** has an additional column which is not in **B** then empty cells in the rows imported from **B** are filled with n/a
- If **A** and **B** share additional columns with identical column name, then they are treated as semantically identical units and merged accordingly.
- In the resulting .janno file, all additional columns from both **A** and **B** are sorted alphabetically and appended after the normal, specified variables.

The following example illustrates the described behaviour:

A.janno

Poseidon_ID	Group_Name	Genetic_Sex	AdditionalColumn1	AdditionalColumn2
XXX011	POP1	M	A	D
XXX012	POP2	F	В	E
XXX013	POP1	M	C	F

B.janno

Poseidon_ID	${\bf Group_Name}$	${\rm Genetic_Sex}$	Additional Column 3	Additional Column 2
YYY022	POP5	F	G	J
YYY023	POP5	F	H	K
YYY024	POP5	M	I	L

A.janno + B.janno

Poseidon_	_ID GroupN	ame Genetic	e_Sex Additional	Column1 Additional	Column2 AdditionalColumn3
XXX011	POP1	Μ	A	D	n/a
XXX012	POP2	\mathbf{F}	В	${ m E}$	n/a
XXX013	POP1	${ m M}$	\mathbf{C}	\mathbf{F}	n/a
YYY022	POP5	\mathbf{F}	n/a	J	G
YYY023	POP5	\mathbf{F}	n/a	K	H
YYY024	POP5	${ m M}$	n/a	${ m L}$	I

2.3.3 Treatment of the .ssf file while merging

The Sequencing Source File (short .ssf file) is forged in exactly the same way as the janno file. SSF files that are present are included in the forge product in the way that the user expects, following selection of those entities which are listed in the poseidon_IDs columns of the SSF files. Columns that are only present in some packages, including those not defined by our [Schema] are also included in the forged product in the same way as described for Janno above.

2.3.4 Treatment of the .bib file while merging

In the forge process all relevant samples for the output package are determined. This includes their .janno entries and therefore the information on the publication keys documented for them in the .janno Publication column. The output .bib file compiles only the relevant references for the samples in the output package. It includes the references exactly once and is sorted alphabetically (by key).

2.3.5 Other options

Just as for init the output package of forge is created as a new directory -o. The title can also be explicitly defined with -n.

--minimal allows for the creation of a minimal output package without .bib and .janno. This is especially useful for data analysis pipelines, where only the genotype data is required. Even more basic output comes with --onlyGeno, which means that only the genotype data is returned without any Poseidon package.

forge has a an optional flag --intersect, that defines, if the genotype data from different packages should be merged with an **union** or an **intersect** operation. The default (if this option is not set) is to output the union of all SNPs, with genotypes defined as missing in samples from packages which do not have a SNP that is present in another package. With this option set, on the other hand, the forged dataset will typically have fewer SNPs, but less missingness.

--intersect also influences the automatic determination of the snpSet field in the POSEIDON.yml file for the resulting package. If the snpSets of all input packages are identical, then the resulting package will just inherit this configuration. Otherwise forge applies the following pairwise merging logic:

Input snpSet A	Input snpSet B	intersect	Ouput snpSet
Other	*	*	Other
1240K	HumanOrigins	True	HumanOrigins
1240K	HumanOrigins	False	1240K

--selectSnps allows to provide forge with a SNP file in EIGENSTRAT (.snp) or PLINK (.bim) format to create a package with a specific selection. When this option is set, the output package will have exactly the SNPs listed in this file. Any SNP not listed in the file will be excluded. If --intersect is also set, only the SNPs overlapping between the SNP file and the forged packages are output.

Merging genotype data across different data sources and file formats is tricky. forge is more verbose about potential issues, if the --logMode flag is set to VerboseLog.

The --onlyGeno command specifies that only genotype data should be output, not an entire Poseidon package.

With --packagewise the within-package selection step in forge can be skipped. This will result in outputting all individuals in the relevant packages, and hence a superset of the requested individuals/groups. It may result in better performance in cases where one wants to forge entire packages.

2.4 Genoconvert command

genoconvert converts the genotype data in a Poseidon package to a different file format. The respective entries in the POSEIDON.yml file are changed accordingly.

Click here for command line details

[-o|--outPackagePath DIR] [--removeOld] [--outPlinkPopName MODE]

Convert the genotype data in a Poseidon package to a different file format

Available options:

-h,--help Show this help text

-d,--baseDir DIR A base directory to search for Poseidon packages. -p,--genoOne FILE One of the input genotype data files. Expects .bed, .bim or .fam for PLINK and .geno, .snp or .ind for EIGENSTRAT. The other files must be in the same

directory and must have the same base name.

--inFormat FORMAT The format of the input genotype data: EIGENSTRAT or

PLINK. Only necessary for data input with --genoFile

+ --snpFile + --indFile.

--genoFile FILE Path to the input geno file. --snpFile FILE Path to the input snp file. --indFile FILE Path to the input ind file.

--snpSet SET The snpSet of the package: 1240K, HumanOrigins or

> Other. Only relevant for data input with -p|--genoOne or --genoFile + --snpFile + --indFile, because the packages in a -d--baseDir already have this

information in their respective POSEIDON.yml files.

(default: Other)

--outFormat FORMAT the format of the output genotype data: EIGENSTRAT or

PLINK.

--onlyGeno Should only the resulting genotype data be returned?

This means the output will not be a Poseidon package.

-o,--outPackagePath DIR Path to the output package directory. This is

> optional: If no path is provided, then the output is written to the directories where the input genotype data file (.bed/.geno) is stored. (default: Nothing) Remove the old genotype files when creating the new

--removeOld

--outPlinkPopName MODE Where to write the population/group name into the FAM

file in Plink-format. Three options are possible: asFamily (default) | asPhenotype | asBoth. See also

--inPlinkPopName.

With the default setting

trident genoconvert -d ... -d ... --outFormat EIGENSTRAT|PLINK

all packages in -d will be converted to the desired --outFormat (either EIGENSTRAT or PLINK), if the data is not already in this format. This includes updating the respective POSEIDON.yml files.

The "old" data is not deleted, but kept around. That means conversion can result in a package with both PLINK and EIGENSTRAT data, but only one is linked in the POSEIDON.yml file, and that is what will be used by trident. To delete the old data in the conversion you can add the --removeOld flag.

Instead of -d to change Poseidon packages, the -p (+ --snpSet) or --inFormat + --genoFile + --snpFile + --indFile (+ --snpSet) allow to directly convert genotype data that is not wrapped in a Poseidon package and store it to a directory given in -o. See this example:

trident genoconvert \

- -p 2018_Mittnik_Baltic/Mittnik_Baltic.bed \
- --outFormat EIGENSTRAT
- -o my_directory

2.5 Rectify command

rectify automatically harmonizes POSEIDON.yml files of one or multiple packages. This is not an automatic update from one Poseidon version to the next, but rather a clean-up wizard after manual modifications.

Click here for command line details

Adjust POSEIDON.yml files automatically to package changes

```
Available options:
```

```
-h,--help
                         Show this help text
-d,--baseDir DIR
                         A base directory to search for Poseidon packages.
--ignorePoseidonVersion
                         Read packages even if their poseidonVersion is not
                         compatible with trident.
--poseidonVersion ?.?.?
                         Poseidon version the packages should be updated to:
                         e.g. "2.5.3".
--packageVersion VPART
                         Part of the package version number in the
                         POSEIDON.yml file that should be updated: Major,
                         Minor or Patch (see https://semver.org).
--logText STRING
                         Log text for this version in the CHANGELOG file.
--checksumAll
                         Update all checksums.
--checksumGeno
                         Update genotype data checksums.
--checksumJanno
                         Update .janno file checksum.
--checksumSSF
                         Update .ssf file checksum
--checksumBib
                         Update .bib file checksum.
--newContributors DSL
                         Contributors to add to the POSEIDON.yml file in the
                         form "[Firstname Lastname] (Email address);...".
```

It can be called with a lot of optional arguments:

```
trident rectify -d ... -d ... \
   --poseidonVersion "X.X.X" \
   --packageVersion Major|Minor|Patch \
   --logText "short description of the update"
   --checksumAll
   --newContributors "[Firstname Lastname](Email address);..."
```

These arguments determine which fields of the POSEIDON.yml file should be modified.

- --poseidonVersion allows a simple change of the poseidonVersion field in the POSEIDON.yml file.
- --packageVersion increments the package version number in the first, the second or the third
 position. It can optionally be called with --logText, which appends an entry to the CHANGELOG
 file for the respective package version update. --logText also creates a new CHANGELOG file if
 it does not exist yet.
- --checksumGeno, --checksumJanno, --checksumSSF and --checksumBib add or modify the respective checksum fields in the POSEIDON.yml file. --checksumAll is a wrapper to call all of them at once.
- --newContributors adds new contributors.

:warning: As rectify reads and rewrites POSEIDON.yml files, it may change their inner order, layout or even content (e.g. if they have fields which are not in the POSEIDON.yml definition). Create a backup of the POSEIDON.yml file before running rectify if you are uncertain if this might affect you negatively.

3 Inspection commands

List command

list lists packages, groups and individuals of the datasets you use, or of the packages available on the server.

Click here for command line details

```
Usage: trident list ((-d|--baseDir DIR) | --remote [--remoteURL URL]
                      [--archive STRING])
                    (--packages | --groups | --individuals
                      [-j|--jannoColumn COLNAME]) [--raw]
```

List packages, groups or individuals from local or remote Poseidon repositories

--raw

Available options: -h,--help Show this help text -d,--baseDir DIR A base directory to search for Poseidon packages. --remote List packages from a remote server instead the local file system. --remoteURL URL URL of the remote Poseidon server. (default: "https://server.poseidon-adna.org") The name of the Poseidon package archive that should --archive STRING be queried. If not given, then the query falls back to the default archive of the server selected with --remoteURL. See the archive documentation at https://www.poseidon-adna.org/#/archive_overview for a list of archives currently available from the official Poseidon Web API. (default: Nothing) --packages List all packages. --groups List all groups, ignoring any group names after the first as specified in the .janno-file. --individuals List all individuals/samples. -j,--jannoColumn COLNAME List additional fields from the janno files, using the .janno column heading name, such as "Country", "Site", "Date_C14_Uncal_BP", etc..

without header. This is useful for piping into grep or awk.

To list packages from your local repositories, as seen above you can run

```
trident list -d ... -d ... --packages
```

This will yield a nicely formatted table of all packages, their version and the number of individuals in them.

Return the output table as tab-separated values

```
You can use --remote to show packages on the remote server. For example
```

trident list --packages --remote --archive "community-archive"

will result in a view of all packages available in one of the public online archives. Just as for fetch, the --archive flag allows to choose which public archive to query.

Independent of whether you query a local or an online archive, you can not just list packages, but also groups, as defined in the third column of EIGENSTRAT .ind files (or the first/last column of a PLINK .fam file), and individuals with the flags --groups and --individuals (instead of --packages).

The --individuals flag additionally provides a way to immediately access information from .janno files on the command line. This works with the -j/--jannoColumn option. For example adding -j Country -j Date_C14_Uncal_BP to the commands above will add the Country and the Date_C14_Uncal_BP columns to the respective output tables.

Note that if you want a less fancy table, for example because you want to load this into Excel, or pipe into another command that cannot deal with the table layout, you can use the --raw option to output that table as a simple tab-delimited stream.

3.2 Summarise command

summarise prints some general summary statistics for a given poseidon dataset taken from the .janno files.

Click here for command line details

```
Usage: trident summarise (-d|--baseDir DIR) [--raw]
```

Get an overview over the content of one or multiple Poseidon packages

Available options:

```
-h,--help Show this help text
```

-d,--baseDir DIR A base directory to search for Poseidon packages.
--raw Return the output table as tab-separated values
without header. This is useful for pining into green

without header. This is useful for piping into grep

or awk.

You can run it with

```
trident summarise -d ... -d ...
```

which will show you context information like – among others – the number of individuals in the dataset, their sex distribution, the mean age of the samples (for ancient data) or the mean coverage on the 1240K SNP array in a table. summarise depends on complete .janno files and will silently ignore missing information.

You can use the --raw option to output the summary table in a simple, tab-delimited layout.

3.3 Survey command

survey tries to indicate package completeness (mostly focused on .janno files) for poseidon datasets.

Click here for command line details

```
Usage: trident survey (-d|--baseDir DIR) [--raw]
```

Survey the degree of context information completeness for Poseidon packages

Available options:

```
-h,--help Show this help text
```

-d,--baseDir DIR A base directory to search for Poseidon packages.
-raw Return the output table as tab-separated values without header. This is useful for piping into grep

or awk.

Running

```
trident survey -d ... -d ...
```

will yield a table with one row for each package. See trident survey -h for a legend which cell of this table means what.

Again you can use the --raw option to output the survey table in a tab-delimited format.

3.4 Validate command

validate checks Poseidon packages and indivudual package components for structural correctness.

Click here for command line details

Check Poseidon packages or package components for structural correctness

```
Available options:
  -h,--help
                           Show this help text
  -d,--baseDir DIR
                           A base directory to search for Poseidon packages.
                           Ignore snp and geno file.
  --ignoreGeno
                           Test parsing of all SNPs (by default only the first
  --fullGeno
                           100 SNPs are probed).
  --ignoreDuplicates
                           Do not stop on duplicated individual names in the
                           package collection.
  -c,--ignoreChecksums
                           Whether to ignore checksums. Useful for speedup in
                           debugging.
  --ignorePoseidonVersion
                           Read packages even if their poseidonVersion is not
                           compatible with trident.
  --pyml FILE
                           Path to a POSEIDON.yml file.
  -p,--genoOne FILE
                           One of the input genotype data files. Expects .bed,
                           .bim or .fam for PLINK and .geno, .snp or .ind for
                           EIGENSTRAT. The other files must be in the same
                           directory and must have the same base name.
  --inFormat FORMAT
                           The format of the input genotype data: EIGENSTRAT or
                           PLINK. Only necessary for data input with --genoFile
                           + --snpFile + --indFile.
                           Path to the input geno file.
  --genoFile FILE
  --snpFile FILE
                           Path to the input snp file.
  --indFile FILE
                           Path to the input ind file.
  --janno FILE
                           Path to a .janno file.
  --ssf FILE
                           Path to a .ssf file.
  --bib FILE
                           Path to a .bib file.
  --noExitCode
                           Do not produce an explicit exit code.
```

You can run it with

trident validate -d ... -d ...

to check packages and it will either report a success (Validation passed) or failure with specific error messages.

Instead of validating entire packages with <code>-d</code> you can also apply it to individual files and package components: <code>--pyml</code> (POSEIDON.yml), <code>-p | --inFormat + --genoFile + --snpFile + --indFile</code> (genotype data), <code>--janno</code> (.janno file), <code>--ssf</code> (.ssf file) or <code>--bib</code> (.bib file). In this case validate attempts to read and parse the respective files individually and reports any issues it encounters. Note that this considers the files in isolation and does not include any cross-file consistency checks.

When applied to packages, validate tries to ensure that each package adheres to the schema definition. Here is a list of what is checked:

- Structural correctness of the POSEIDON.yml file.
- Presence of all files references in the POSEIDON.yml file.
- Full structural correctness of .janno, .ssf and .bib file.
- Superficial correctness of genotype data files by parsing the first 100 SNPs. A full check that parses all SNPs can be triggered with the --fullGeno option. --ignoreGeno, on the other hand, causes validate to ignore the genotype data entirely, which speeds up the validation significantly.
- Correspondence of BibTeX keys in .bib and .janno
- $\bullet\,$ Correspondence of sample IDs in .janno and .ssf.
- Correspondence of sample and group IDs in .janno and genotype data files.

In fact much of this validation already runs as part of the general package reading pipeline invoked for other trident subcommands (e.g. forge). validate is meant to be more thorough/brittle, though, and will explicitly fail if even a single package is broken. For special cases more flexibility can be enabled with the options --ignoreDuplicates, --ignoreChecksums and --ignorePoseidonVersion.

Remember to run validate it with --debug to get more information in case the default output is not sufficient to analyse an issue.
